## Proof of suitability of a water mist fire protection system in a hotel atrium as compensatory measure combining different engineering methods

R. Rothe, R. Lehmann

- Introduction
- Description of Methodology
- Results and Discussion

# Introduction

- Aim: proof of fire protection for hotel atrium
- Conclusion: water mist system as compensatory measure will be verified using engineering methods

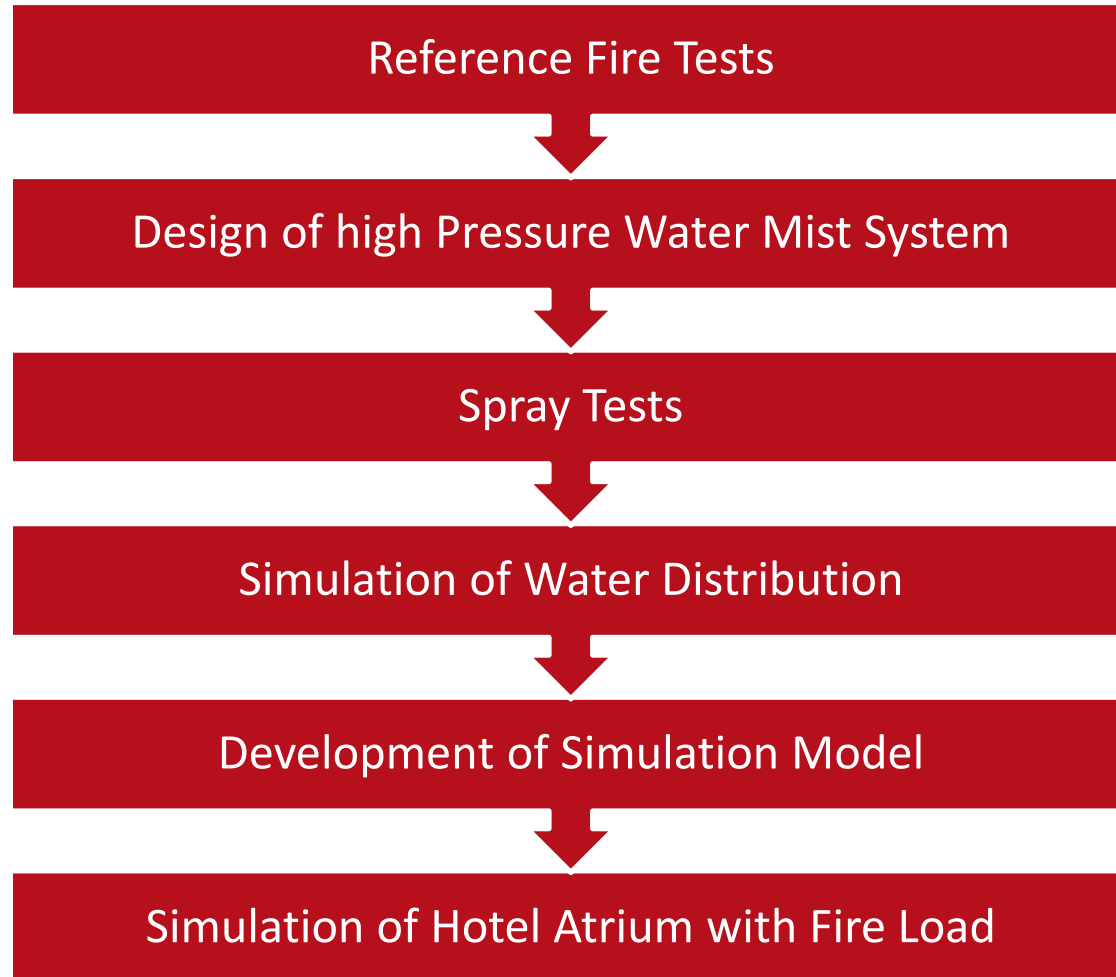

# Introduction

- Height of 27m, diameter appr. 16m
- Cross section rejuvenates above 22m
- Glass facade from 5m to 22m

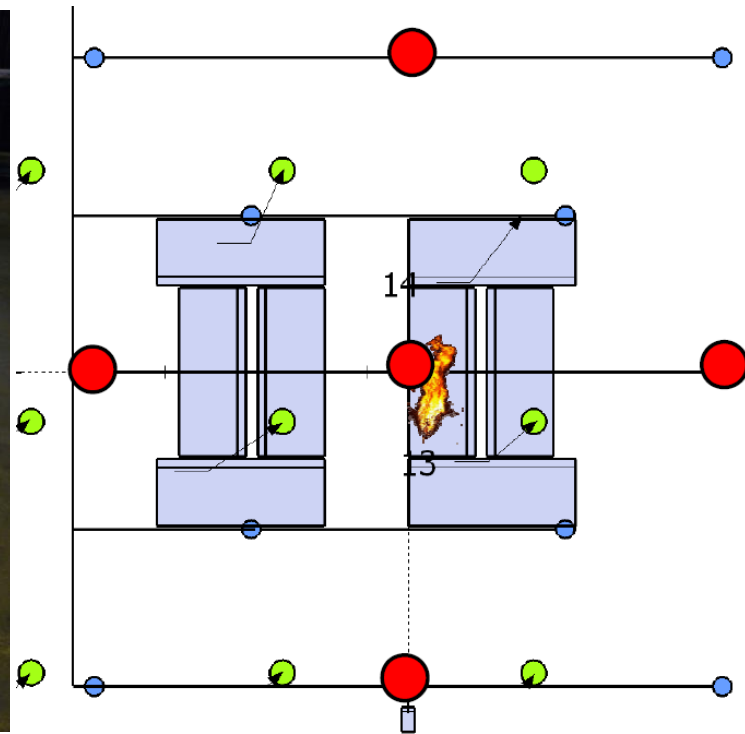

# Methodology - Overview

# Methodology – Reference Fire Tests

- IFAB has test data for comparable scenario
  - 12m height, uniform nozzle grid
  - Public open space scenario based on IMO RES A.800
  - 8 polyether foam mattresses on sofas

# Methodology – Reference Fire Tests

- Performance criteria:
  - No damage to the target
  - Reduction temperature at the ceiling/in vicinity of the fire
  - Reduction of radiative heat
  - Control/suppress fire

→ For evaluation of performance, only ceiling temperatures will be considered

# Methodology – Reference Fire Tests

- Design of water mist system was adopted from reference fire tests
  - Similar fire-fighting performance is expected with a system that has comparable design parameters
  - Results of fire tests allow validation and calibration of CFD model used for evaluation
- Differences:
  - Height of room
  - Different orientation of nozzles
  - Nozzle layout is different due to geometrical limitations
- Relevant parameters of HPWM system:
  - Amount of water applied to area
  - Spray dynamics and droplet size (→ quality of water mist)

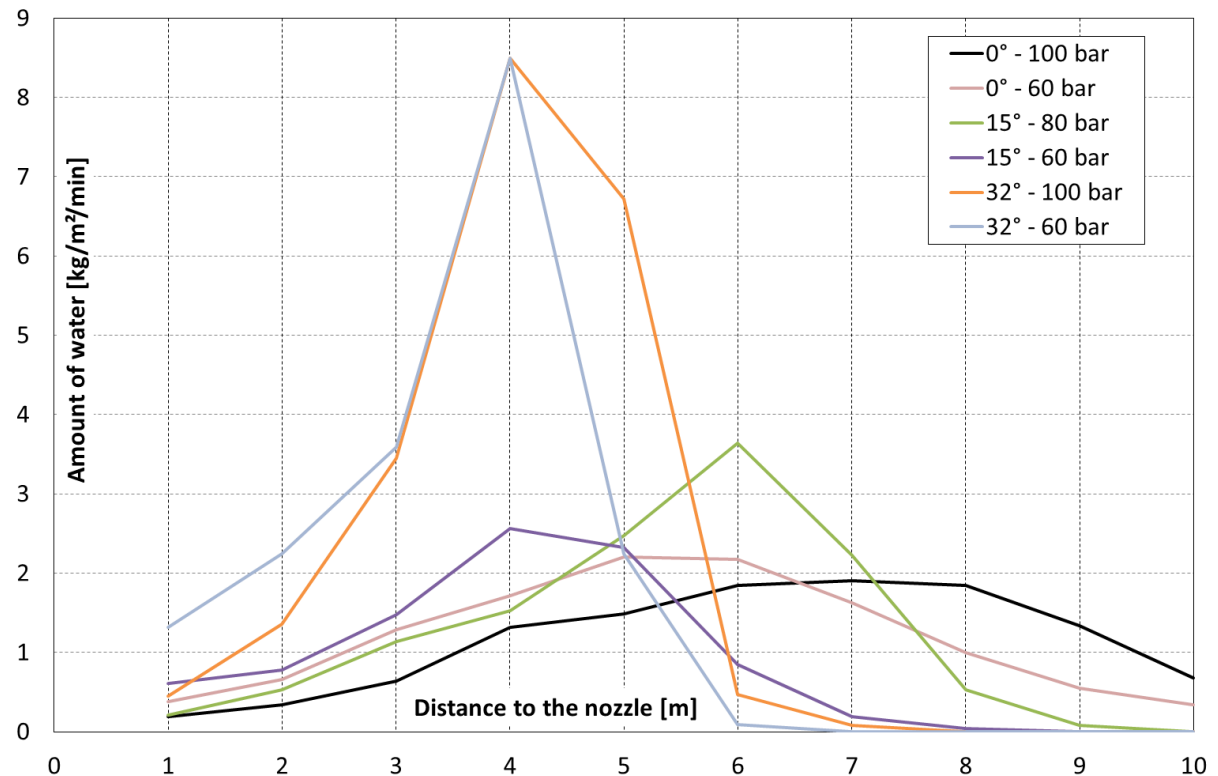

# Methodology – Spray Tests

- Spray tests with a single nozzle
- Varied design parameters:
  - Angle of installation
  - Design pressure
- Desired properties of water distribution on the floor:
  - High reach of water mist with high momentum
  - Uniform distribution on the whole range

# Methodology – Spray Tests

- Decision: spray angle:  $0^\circ$ ; design pressure: 100 bar
- Spray tests also necessary for calibration/validation of CFD model
  - Velocity
  - Spray angle

# Methodology – Distribution of Water Mist

- Problem: Amount of water is sufficient for atrium, but it needs to be shown, that water is distributed evenly with all nozzles
  - Necessary prerequisite to transfer results from fire tests
- Approach: Use calibrated nozzle, implement HPWM design in CFD model and simulate water distribution

# Excursus - Fire Dynamics Simulator

- Open-source software with huge community and extensive database of validation and verification works
- „FDS solves numerically a form of the Navier-Stokes equations appropriate for low-speed, thermally-driven flow with an emphasis on smoke and heat transport from fires.“ (FDS User Guide)
- Simulation of particles (water mist) as Lagrangian particles

# Methodology – Distribution of Water Mist

# Methodology – Distribution of Water Mist

- Results: Most of atrium is covered well with water
- Areas influenced by ventilation covered with less water
- However: If fire starts in area with less water, flow of hot air will be deflected towards center of atrium, which is covered well with water

# Methodology – Development of CFD-Model

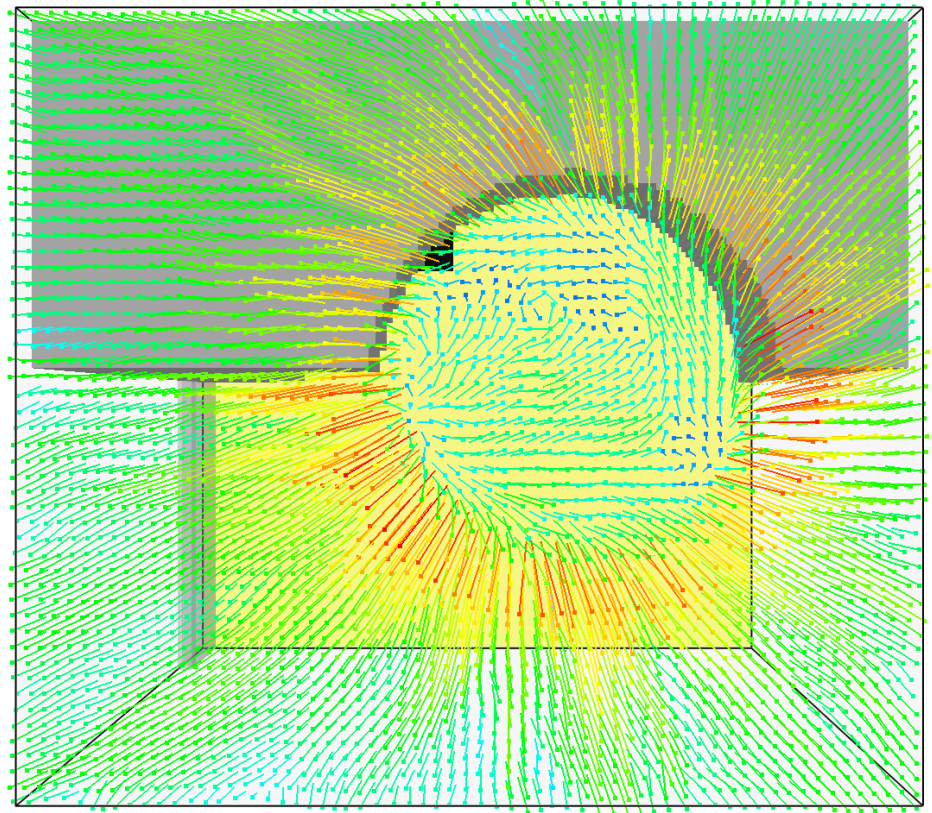

- Geometry approximated with block structure

# Methodology – Development of CFD-Model

- Smoke evacuator on top of the atrium activates in case of fire, arranged symmetrically on top
- Ventilation openings (doors) in lobby allow air to move in atrium for balancing air

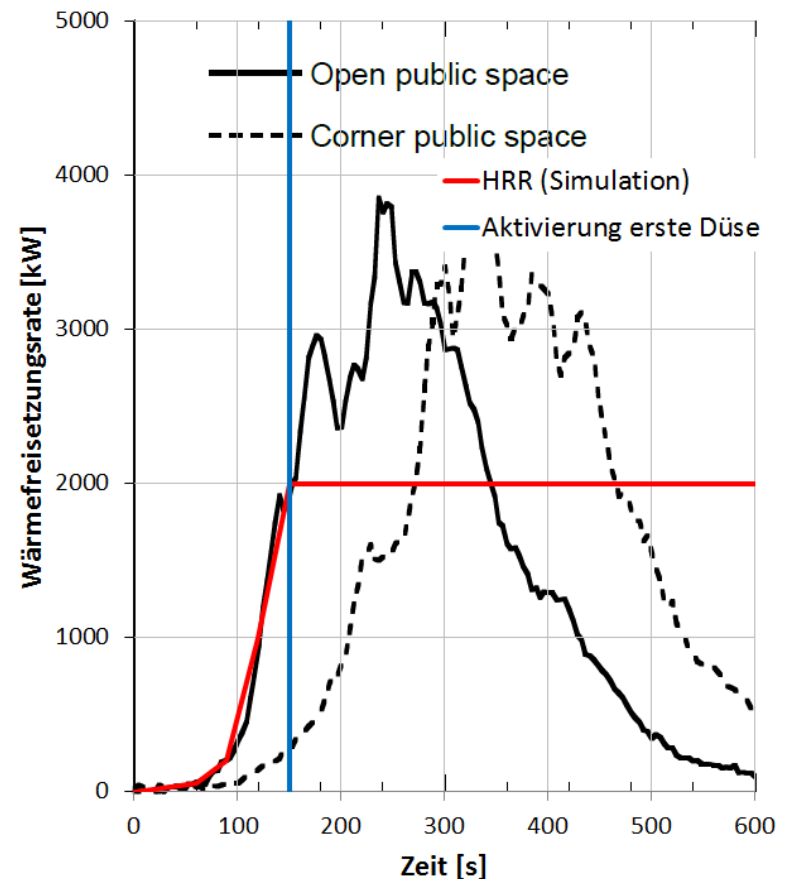

# Methodology – Development of CFD-Model

- Heat release rate of IMO open-space fire load was used (Arvidsson 2014)
- Two different (critical) locations of fire load (with regard of expected thermal stress of glass facade) were assumed

# Methodology – Validation of CFD-Model

- Model was used to simulate reference fire tests in order to validate
- Reasons:
  - complex case
  - plausibility check for mistakes made by user
- Assumption: Heat release rate remains constant after activation of first nozzle

# Methodology – Validation of CFD-Model

- Results: FDS is sufficiently capable of simulation of suppression of temperature of water mist system using OH1 fire load

# Methodology – Simulation of Atrium

- Surface temperature remains below 60°C throughout whole simulation
- Design of HPWM is sufficient to protect glass facade of atrium

# Results and Discussion

- Successful approach of proving performance of HPWM system was shown
  - Accepted by German building authority
- Only possible due to fire tests with comparable scenario (experimental data with the same nozzle and similar fire load)
- In general, proving performance of HPWM system is not possible with simulations only
- Strongly recommended, to question results from CFD
- When in doubt, results of CFD-simulations should be waived

## Results and Discussion – Why Validation?

- Due to validation, an error in FDS 6.1.2 was detected
  - Simulation of very fine droplets results in too high temperature
  - Bug allows temperature of droplets to overshoot ambient air temperature (under discussion with developers)
- Use of FDS 5.5.3 for simulations, which showed good agreement of fire test and simulation

# Results and Discussion – Why Validation?

FDS 5.5.3

# Results and Discussion – Why Validation?

FDS 6.1.2
